# Decomposition Approach to Minimize a Class of Superposition of Recurrent Monotone Functions on a Set of Parameterized Paths in Digraph 

Nikolai Guschinsky and Genrikh Levin<br>Institute of Engineering Cybernetics, National Academy of Sciences of Belarus, Surganova str., 6, 220012 Minsk, Belarus

#### Abstract

A problem of finding optimal parameterized path in digraph is considered. A parameterized path is a path each arc of which is assigned a parameter from a given set. A superposition of recurrent-monotone functions is accepted as an objective function where one of the functions is defined by using max operation. A twolevel decomposition scheme for solving an initial problem is proposed. Methods for solving the obtained after decomposition subproblems are developed.

## 1. Introduction

Problems of finding optimal paths often arise in design and analysis of various networks. Shortest path problem is one of the most well-known such problems. A lot of papers is devoted to this problem (see, for instance, bibliography in [1, 2]). Last decades formulations of these problems with complex objective functions are intensively studied. Sometimes such problems arise when reducing multicriteria problems to a problem with one so-called generalized criterion which is in fact a superposition of partial criteria. This paper focuses on a class of such problems.

In the section 2, the considered problem is formulated. In the section 3, a twolevel decomposition scheme for solving the initial problem is proposed. In the following sections, methods for solving subproblems obtained after decomposition are developed taking into account their features.

## 2. Statement of the problem

Let $G=(V, E)$ be a finite directed graph with distinguished vertices $s$ and $t$ without multiple arcs. Each arc $(v, p) \in E$ is assigned a set $\Gamma_{v p}$ and a vector-
function $\quad c_{v p}(\alpha)=\left(c_{v p}^{1}(\alpha), c_{v p}^{\frac{1}{3}}(\alpha), c_{v p}^{J}(\alpha)\right) \quad$ where $\alpha \in \Gamma_{v p}$ and $c_{v p}^{\prime}(\alpha), r=1,2,3$, are non-negative realvalued functions.

A pair $x=(w, \gamma)$ is a parameterized path in graph $G$, if $w=\left(\mathrm{i}_{0}, \mathrm{~K}, \mathrm{i}_{1}\right)$ is a path in graph G and $\gamma=\left(\gamma_{l}, \mathrm{~K}, \gamma_{l}\right) \in \Gamma(w)=\prod_{l=1}^{l} \Gamma_{i_{k-l} i_{k}}$.

On a set $X_{v}$ of parameterized paths in graph $G$ from the vertex $s$ to a vertex $v \in V$, the following functions are defined:

$$
\begin{aligned}
& f^{l}(x)=\max \left\{c_{i_{k-l} i_{k}}^{l}\left(\gamma_{k}\right) \mid l \leq k \leq l\right\}, \\
& f^{r}(x)=\sum_{k=1}^{l} c_{i_{k-l}, l i_{k}}^{r}\left(\gamma_{k}\right), r=2,3
\end{aligned}
$$

An initial problem $\mathbf{A}$ is to find a parameterized path $x^{*}=\left(w^{*}, \gamma^{*}\right) \in X=X_{t}$, which minimizes a function $g(x)=f^{l}(x)-f^{2}(x)+f^{3}(x)$.

## 3. Decomposition scheme

For solving the problem $\mathbf{A}$, the following decomposition scheme can be used. It is a concrete definition of a general scheme for solving similar class of problems $[3,4,5]$.

Let us introduce a set $Y \subset R$ such that

$$
Y \cap\left\{f^{l}(x) \mid x \in X^{*}\right\} \neq \varnothing
$$

and

$$
\left[\min \left\{f^{I}(x) \mid x \in X\right\}, \max \left\{f^{l}(x) \mid x \in X\right\}\right] \supseteq Y
$$

where $X^{*}$ is a set of solutions of the problem $\mathbf{A}$, and a function $g^{0}(x, y)=y \cdot f^{2}(x)+f^{3}(x)$ which is defined on $X \times Y$.

Fig.1. Decomposition scheme for solving the initial problem $\mathbf{A}$

At a lower level, for fixed value of parameter $y \in Y$ we solve (possible approximate to a criterion $\left.f^{l}(x)\right)$ local problems $\quad \mathbf{B}^{\prime}(y)$ of lexicographic minimization

$$
\begin{gathered}
\left(g^{0}(x, y), f^{l}(x)\right) \rightarrow \text { Lex min } \\
x \in X(y)=\left\{x \in X \mid f^{J}(x) \leq y\right\}
\end{gathered}
$$

and at upper level, we solve problem $\mathbf{B}^{\prime \prime}$ :

$$
\begin{aligned}
& F(y)=g\left(x^{*}(y)\right) \rightarrow \min \\
& y \in Y
\end{aligned}
$$

where $x^{*}(y)$ is an obtained solution of the problem $\mathbf{B}^{\prime}(\mathrm{y})$,

Solution $x^{*}(y)=(w, \gamma)$ can be "improved" after solving an auxiliary problem $\mathbf{C}(\mathrm{w})$ :

$$
g((w, \gamma)) \rightarrow \min ,
$$

$\gamma \in \Gamma$.
Diagram of this procedure is shown in Fig. 1.
Proposition 1. If y is a $\varepsilon$-approximate solution of the problem $\mathbf{B}^{\prime \prime}$, then $\mathrm{x}^{*}(\mathrm{y})$ is a $\varepsilon$-approximate solution of the problem $\mathbf{A}$.

It should be noted that if sets $\Gamma_{v p}$ are finite for all $(\nu, p) \in E$, then the problem $\mathbf{A}$ is polynomially (with regard to dimensions of graph $G$ ) solvable.

## 4. Solving the problem B*

For solving the problem $\mathbf{B}^{\prime \prime}$ we propose to use the following modification of "branch and bound method" which takes into account non-unimodality of function $\mathrm{F}(\mathrm{y})$ on Y .

To a current step of an algorithm, a value $y^{0}$ and a current record $F^{0}=F\left(y^{\circ}\right)$ of function $F(y)$ on $Y$ are known as well as from the initial set $Y$ a set $Y^{0}$ is extracted such that $\min \left\{F(y) \mid y \in Y^{0} \mathrm{U}\left\{y^{0}\right\}\right\}-F^{*} \leq$ $\varepsilon$ where $F^{*}=\min \{F(y) \mid y \in Y\}$ and $\varepsilon$ is a required accuracy (with regard to objective function) for solution of problem $\mathbf{A}$. The set $Y^{0}$ is divided into subsets $Y_{i}$ contained in disjoint intervals ( $y_{i}^{-}, y_{i}$ ).

At the current step, a value $y^{\prime}$ is chosen in a set $Y_{i}$ for which problem $\mathbf{B}^{\prime}\left(y^{\prime}\right)$ is solved and parameterized path $x^{*}(y)=\left(w^{*}(y), \gamma^{*}(y)\right)$ is found. The problem $\mathrm{C}(\mathrm{w})$ for $w^{*} w^{*}(y)$ is solved (if
necessary). It results in correction of values $y^{0}$ and $F^{0}$, replacing the set $Y_{i}$ by its subsets $Y_{i d}=\left\{y \in Y_{1} \mid y<y^{\prime}\right\} \quad$ and $\quad Y_{i_{2}}=\left\{y \in Y_{;} \mid y>y^{\prime}\right\}$. After that for each subset $Y_{i}$ of $Y^{0}$, a value $z_{j}$ is defined in such a way that either $F(y)>F^{0}-\varepsilon$ for $z_{1} \leq y \leq y_{i}^{+}$or there exists $y^{\prime}<z_{l}$ for which $F(y) \leq F(y)$. Subset $\left[z_{1}, y_{l}^{+}\right]$is deleted from the set $Y_{i}$.

A choice of next $Y_{i}$ can be performed using various heuristics which take into account such characteristics of sets $Y_{I}$ as bounds of function $F(y)$ on the set $Y_{i}$, length of interval $\left(y_{i}^{-}, y_{i}^{+}\right)$and etc.

$$
\begin{aligned}
& \text { Since } \\
& \min \left\{F(y) \mid y \in Y_{i}, f^{l}\left(x^{*}(y)\right)>y_{i}^{-}\right\} \geq \\
& \min \left\{g^{0}(x, y) \mid y \in Y_{i}\right\}
\end{aligned}
$$

then either a lower bound $q_{i}$ of $g^{0}(x, y)$ is also a lower bound of $F(y)$ on $Y_{i}$ or there exists $z<y_{i}^{-}$such that $F(z)<\min \left\{F(y) \mid y \in Y_{i}\right\}$. In the latter case, eliminating $Y_{i}$ from the set $Y$ does not result in loss of solution to the problem $\mathbf{B}^{\prime \prime}$. It allows also to use $q_{t}$ as lower bound of $F(y)$ on $Y_{i}$.

In particular, we can consider

$$
q_{1}=\max \left[g^{\prime}-\left(y^{\prime}-y_{1}^{-}\right) \beta_{i}^{2}, g^{\prime} y_{i}^{-} / y^{\prime}+\beta_{i}^{3}\left(1-y_{i}^{-} / y\right)\right]
$$

where $\beta_{\mathrm{i}}^{2}$ is an upper bound of function $f^{\frac{3}{2}}(x)$ and $\beta_{i}^{3}$ is a lower bound of function $f^{3}(x)$ on the set $\left\{x \in X_{i} \mid y_{i}^{-}<f^{I}(x)<y_{i}^{+}\right\}$. The eliminated set $\left[z_{i}, y_{i}^{+}\right]$can be defined as

$$
z_{i}=\min \left[y^{\prime}-\left(g^{\prime}-F^{0}\right) / \beta_{i}^{2}, y^{\prime}\left(g^{\prime}-F^{0}\right) /\left(g^{\prime}-\beta_{i}^{3}\right)\right]
$$

It should be noted that if the bound $\beta_{i}^{3}$ is accessible then its use is preferable in comparison with $\beta_{i}$.

## 5. Solving the problem $B^{\prime}(y)$

A general scheme for solving the problem $\mathbf{A}$ requires to solve a sequence of problem $B^{\prime}(y)$ for some sequence $\left\{y_{1}\right\}$ of parameters $y \in Y$, which is generated during solving the problem $\mathbf{B}^{\prime \prime}$. It results in a development of special methods for solving problems $B^{\prime}(y)$ which take into account their parametric properties. Methods proposed hereafter allow to use for solving the current problem $\mathbf{B}^{\prime}(y)$ data which have
already been obtained during solving problems $\mathbf{B}^{\prime}(\mathbf{y})$ for the nearest lesser and greater values to $y$ from the sequence $\left\{y_{1}\right\}$. Such approach is very effective if calculation of functions $c_{\nu p}^{r}(0)$ is time consuming.

It is easy to see that for the problem $\mathbf{B}^{\prime}(\mathrm{y})$ one may consider instead the graph $G$ a graph $G(y)=(V(y)$, $E(y)$ ) which is obtained from the graph $G$ by eliminating arcs $(\nu, p) \in E$ such that $c_{v p}^{l}(\alpha)>y$ for all $\alpha \in \Gamma_{\nu p}$ and vertices that are not accessible from $s$ and counteraccessible from $t$.

Proposition 2. If $z_{1}, z_{2} \in\left\{y_{1}\right\}, z_{1}<z_{2}$ and $x_{k}=\arg \min \left\{g^{0}\left(x, z_{k}\right) \mid x \in X\left(z_{k}\right)\right\}, k=1,2$, then
i) $f^{2}\left(x_{1}\right) \geq f^{2}\left(x_{2}\right)$ and $f^{3}\left(x_{1}\right)<f^{3}\left(x_{2}\right)$;
ii) $f^{2}\left(x_{l}\right)=f^{2}\left(x_{2}\right)$ iff $f^{3}\left(x_{l}\right)=f^{3}\left(x_{2}\right)$;
iii) if $f^{2}\left(x_{I}\right)=f^{2}\left(x_{2}\right)$ and for $k=1,2$,

$$
\left(g^{0}\left(x, z_{k}\right), f^{l}\left(x_{k}\right)\right)=
$$

Lex $\min \left\{\left(g^{0}\left(x, z_{k}\right), f^{l}(x)\right) \mid x \in X\left(z_{k}\right)\right\}$,
then $f^{l}\left(x_{1}\right)=f^{l}\left(x_{2}\right)$.
It allows us to use the earlier obtained data in the following way.

Let us consider collections
$H^{n}(y)=\left\{h_{p}^{n}(y) \mid p \in V(y)\right\}$ of vectors

$$
h_{p}^{n}(y)=\left(h_{p}^{n, I}(y), h_{p}^{n, 2}(y), h_{p}^{n, 3}(y)\right), n=1,2,3
$$

such that $h_{7}^{n}(y)=(0,0,0)$ and for all $p \in V(y) \backslash\{s\}$ the following recurrent relationships are satisfied:

$$
\begin{aligned}
h_{p}^{\prime}(y)=\arg \text { lex } \min \{ & \left(y \cdot \lambda^{2}+\lambda^{3}, \lambda^{l}\right) \\
& \left.\left(\lambda^{l}, \lambda^{2}, \lambda^{3}\right) \in Z_{p}^{n}(y)\right\}(1)
\end{aligned}
$$

moreover if $h_{p}^{n}(y) \neq h_{p}^{\prime}\left(y_{p}^{\prime \prime}(y)\right)$, then there exists a parameterized path

$$
x_{p}^{\prime \prime}\left(H_{p}^{\prime \prime}(y)\right)=\left(\left(v=i_{0}, \mathrm{~K}, i_{l}\right),\left(\gamma_{1}, \mathrm{~K}, \gamma_{l}\right)\right)
$$

such that $h_{v}^{n}(y)=h_{v}^{n}\left(y_{v}^{n}(y)\right)$ and for $k-l_{\ldots}, \ldots$
$h_{i_{k}^{\prime \prime}}^{\prime \prime}(y)=\max \left(h_{k-1}^{n, l}(y), c_{i_{k-l} l_{k}}^{l}\left(\gamma_{k}\right)\right) \neq h_{i_{k}}^{n_{1} l}\left(y_{i k}^{n}(y)\right)$
$\left.h_{i, k}^{n, r}(y)=h_{i k-l}^{n, r}(y)+c_{i k-l l_{k}}^{r}\left(\gamma_{k}\right)\right) \neq h_{i k}^{n, r}\left(y_{i k}^{n}(y)\right)$, $r=2,3$. Here
$Z_{p}^{n}(y)=\left\{h_{p}^{n}\left(y_{p}^{n}(y)\right)\right\} \cup\left\{\left(\max \left(h_{v}^{n, l}(y), c_{\nu p}^{l}(\alpha)\right)\right.\right.$,
$\left.\left.h_{v}^{n, 2}(y)+c_{v p}^{2}(\alpha), h_{v}^{n, 3}(y)+c_{v p}^{3}(\alpha)\right) \mid(\nu, \alpha) \in Q_{p}^{n}(y)\right\}$

$$
\begin{aligned}
Q_{p}^{\prime}(y) \subseteq Q_{p}(y)=\{(v, \alpha) \mid & (v, p) \in E(y) \\
& \left.\alpha \in \Gamma_{v p}, c_{v p}^{l}(\alpha) \leq y\right\}
\end{aligned}
$$

The value $y_{p}^{n}(y)$ and the sets $Q_{p}^{n}(y), n=1,2,3$, $p \in V(y)$, are defined as:
a) for $n=2,3$ and $h_{v}^{n, l}\left(y^{r}(y)\right) \leq y$,

$$
\begin{aligned}
& y_{p}^{n}(y)=y^{r}(y) \\
& \left\{(v, \alpha) \in Q_{p}(y) \mid c_{v p}^{2}(\alpha)<h_{p}^{n, 2}\left(y^{r}(y)\right)-h_{v}^{n, 2}(y)\right. \\
& \left.c_{v p}^{3}(\alpha)>h_{p}^{n .3}\left(y^{r}(y)\right)-h_{v}^{n, 3}(y)\right\} \subseteq Q_{p}^{n}(y)
\end{aligned}
$$

b) for $n=3$ and $h_{v}^{3 / 1}\left(y^{r}(y)\right)>y$ or $n=1$

$$
\begin{aligned}
& y_{p}^{n}(y)=y^{l}(y) \\
& \left\{(v, \alpha) \in Q_{p}(y) \mid c_{v p}^{2}(\alpha)>h_{p}^{n, 2}\left(y^{l}(y)\right)-h_{v}^{n, 2}(y)\right. \\
& c_{v p}^{3}(\alpha)<h_{p}^{n, 3}\left(y^{l}(y)\right)-h_{v}^{n, 3}(y) \text { or } \\
& \left.c_{v p}^{l}(\alpha)>y \text { or } h_{v}^{n, l}(y)>y^{l}(y)\right\} \subseteq Q_{p}^{n}(y)
\end{aligned}
$$

c) otherwise $y_{p}^{\prime \prime}(y)$ is not defined and $Q_{p}^{*}(y)=Q_{p}(y)$.

It is easy to prove
Proposition 3. For all $y \in\left\{y_{l}\right\}, n=1,2,3$, and $p \in V(y)$
$\left(y h_{p}^{n-2}(y)+h_{p}^{n .3}(y), h_{p}^{n .1}(y)\right)=$
Lex $\min \left\{\left(y \cdot f^{2}(x)+f^{3}(x), f^{l}(x) \mid x \in X, f^{l}(x) \leq y\right\}\right.$.
For any vertex $p \in V(y), n=1,2,3$, we can construct a parameterized route $x_{p}^{\prime \prime}(y)$, which consists of $d$ ( $d>1$ ) parameterized paths
$x_{p_{m t}}^{n}=x_{p_{m}}^{n}\left(1 i_{p}^{n}\left(y_{\mu_{m m}}\right)\right)=\left(\left(v_{m}=i_{m 0}, \mathrm{~K}, t_{m l_{m}}\right)\right.$, $\left(\gamma_{m l}, K \cdot \eta_{m=m} l l\right.$, obtained for some $y_{u_{m}} \in\left\{y_{1}\right\}$ such that $v_{l}=s, p_{u_{d}}=p, \quad h_{p}^{\prime}\left(y_{u_{d}}\right)=h_{p}^{\prime \prime}(y) \quad$ and $\quad u_{m-1}<u_{m}$, $p_{m-1}=v_{m}, h_{v_{m}}^{n}\left(y_{v_{m-1}}\right)=h_{v_{m}}^{n}\left(y_{v_{m}}\right)$ for $m=2, \ldots, d$.

It is easy to prove that $x_{p}^{n}(y)$ is a parameterized path if in relationships (1) we accept $h_{p}^{n}(y)=h_{p}^{n}\left(y_{p}^{n}(y)\right)$ iff $Z_{p}^{n}(y)$ does not contain a vector $\left(\lambda^{4}, \lambda^{2}, \lambda^{3}\right)$ such that $\left(y \cdot h_{p}^{n, 2}\left(y_{p}^{n}(y)\right)+h_{p}^{n 3}\left(y_{p}^{n}(y)\right), h_{p}^{n, 1}\left(y_{p}^{n}(y)\right)\right)=$

$$
\left(y \cdot \lambda^{2}+\lambda^{3}, \lambda^{l}\right)
$$

## 6. Conclusions

For solving the problem $\mathbf{C}(w)$, a twolevel procedure can be used, which is similar to the proposed one for the initial procedure $\mathbf{A}$. Inclusion the problem $\mathbf{C}(w)$ into general procedure for solving the initial problem A allows us to obtain "good" upper bounds of function $F(y)$. Taking into account such role of the problem $\mathbf{C}(w)$, it is sufficient to obtain its approximate solution. Furthermore, we can solve it even for some subpath containing vertex $t$.

The proposed approach can be improved for particular applications. For instance, it is possible to reduce the sets $\Gamma_{v p}$ during solving problems $\mathbf{B}^{\prime}(\mathbf{y})$.

The proposed approach can also be extended for more wide class of such problems. For example, a problem when function $f^{l}(x)$ is defined both operation "max" and "min" can be reduced [3] to the considered problem.
